FINAL SECTION: LIST OF ABSTRACTS

A FULL-BODY MODEL OF BURN PATHOPHYSIOLOGY AND TREATMENT USING THE BIOGEARS ENGINE

- We have created a model of systemic burn pathophysiology by incorporating a mathematical model of acute inflammation within the BioGears Engine. This model produces outputs consistent with burns of varying severities and leverages existing BioGears functionality to simulate the effect of treatment on virtual patient outcome. The model performs well for standard resuscitation scenarios and we thus expect it to be useful for educational and training purposes.

A WHOLE-BODY MATHEMATICAL MODEL OF SEPSIS PROGRESSION AND TREATMENT DESIGNED IN THE BIOGEARS PHYSIOLOGY ENGINE

- Sepsis is a debilitating condition associated with a high mortality rate that greatly strains hospital resources. Though advances have been made in improving sepsis diagnosis and treatment, our understanding of the disease is far from complete. Mathematical modeling of sepsis has the potential to explore underlying biological mechanisms and patient phenotypes that contribute to variability in septic patient outcomes. We developed a comprehensive, whole-body mathematical model of sepsis pathophysiology using the BioGears Engine, a robust open-source virtual human modeling project. We describe the development of a sepsis model and the physiologic response within the BioGears framework. We then define and simulate scenarios that compare sepsis treatment regimens. As such, we demonstrate the utility of this model as a tool to augment sepsis research and as a training platform to educate medical staff.

OPEN SOURCE PHARMACOKINETIC/PHARMACODYNAMIC FRAMEWORK: TUTORIAL ON THE BIOGEARS ENGINE

- BioGears is an open-source, lumped parameter, full-body human physiology engine. Its purpose is to provide realistic and comprehensive simulations for medical training, research, and education. BioGears incorporates a physiologically based pharmacokinetic/pharmacodynamic (PK/PD) model that is designed to be applicable to a diversity of drug classes and patients and is extensible to future drugs. In addition, BioGears also supports drug interactions with various patient insults and interventions allowing for a realistic research framework and accurate dose-patient responses. This tutorial will demonstrate how the generic BioGears PK/PD model can be extended to a new substance for prediction of drug administration outcomes.

A MULTISCALE COMPUTATIONAL MODEL OF ANGIOGENESIS AFTER TRAUMATIC BRAIN INJURY, INVESTIGATING THE ROLE LOCATION PLAYS IN VOLUMETRIC RECOVERY

- Vascular endothelial growth factor (VEGF) is a key protein involved in the process of angiogenesis. VEGF is of particular interest after a traumatic brain injury (TBI), as it re-establishes the cerebral vascular network in effort to allow for proper cerebral blood flow and thereby oxygenation of damaged brain tissue. For this reason, angiogenesis is critical in the progression and recovery of TBI patients in the days and weeks post injury. Although well established experimental work has led to advances in our understanding of TBI and the progression of angiogenesis, many constraints still exist with existing methods, especially when considering patient progression in the days following injury. To better understand the healing process on the proposed time scales, we develop a computational model that quickly simulates vessel growth and recovery by coupling VEGF and its interactions with its associated receptors to a physiologically inspired fractal model of the microvascular re-growth. We use this model to clarify the role that diffusivity, receptor kinetics and location of the TBI play in overall blood volume restoration in the weeks post injury and show that proper therapeutic angiogenesis, or vasculogenic therapies, could speed recovery of the patient as a function of the location of injury.

BIOGEARS: A C++ LIBRARY FOR WHOLE BODY PHYSIOLOGY SIMULATIONS

- BioGears is an open source, extensible human physiology computational engine that is designed to enhance medical education, research, and training technologies. BioGears is primarily written in C++ and uses an electric circuit analog to characterize the fluid dynamics of the cardiopulmonary system. As medical training requirements become more complex, there is a need to supplement traditional simulators with physiology simulations. To this end, BioGears provides an extensive number of validated injury models and related interventions that may be applied to the simulated patient. In addition, BioGears compiled libraries may be used for computational medical research to construct in-silico clinical trials related to patient treatment and outcomes. Variable patient inputs support diversity and specification in a given application. The engine can be used standalone or integrated with simulators, sensor interfaces, and models of all fidelities. The Library, and all associated projects, are published under the Apache 2.0 license and are made available through the public GitHub repository. BioGears aims to lower the barrier to create complex physiological simulations for a variety of uses and requirements

BURN CARE TABLET TRAINER TO ENHANCE BURN INJURY CARE AND TREATMENT

- Applied Research Associates (ARA) and the United States Army Institute of Surgical Research (USAISR) have been developing a tablet-based simulation environment for burn wound assessment and burn shock resuscitation. This application aims to supplement the current gold standard in burn care education, the Advanced Burn Life Support (ABLS) curriculum. Subject matter experts validate total body surface area (TBSA) identification and analysis and show that the visual fidelity of the tablet virtual patients is consistent with real life thermal injuries. We show this by noting that the error between their burn mapping and the actual patient burns was sufficiently less than that of a random sample population. Statistical analysis is used to confirm this hypothesis. In addition a full body physiology model developed for this project is detailed. Physiological results, and responses to standard care treatment, are detailed and validated. Future updates will include training modules that leverage this model. We have created an accurate, whole-body model of burn TBSA training experience in Unreal 4 on a mobile platform, provided for free to the medical community. We hope to provide learners with more a realistic experience and with rapid feedback as they practice patient assessment, intervention, and reassessment.

WHOLE BODY PBPK MODEL OF NASAL NALOXONE ADMINISTRATION TO MEASURE REPEAT DOSING

- Opioid use in the United States and abroad is an endemic part of culture with yearly increases in overdose rates and deaths. As rates of overdose incidence increases, the use of the safe and effective reversal agent, Naloxone, in the form of a nasal rescue spray is being fielded and used by emergency medical technicians (EMTs) at a greater and greater rate. Despite advances in deployment of these rescue products, deaths are continuing to increase. There is evidence that repeated dosing of a Naloxone nasal spray (such as Narcan) is becoming more common due to the amount and type of opiate being abused. Although there is strong evidence of the benefits of Naloxone related to opioid reversals there are still not repeated dosing guidelines, as a function of opiate and amount the patient has taken. Goal directed dosing is promising, where respiratory markers are being used as an indication of the patient recovery but require time and understanding by the EMT. We construct a whole-body model of the pharmacokinetics and dynamics of opiates (Morphine and Fentanyl) on respiratory depression. We then construct a model of nasal deposition and administration of naloxone to investigate repeat dosing requirements for large overdoses and analyze how the two opiates may influence these requirements. We show that naloxone is highly effective at reversing respiratory symptoms of the patient and recommend dosing requirements as a function of opiate and amount administered. By designing the model to include circulation and respiration we investigate physiological markers that may be used in goal directed therapy rescue treatments.

INCREASING REALISM AND VARIETY OF VIRTUAL PATIENT DIALOGUES FOR PRENATAL COUNSELING

EDUCATION THROUGH A NOVEL APPLICATION OF CHATGPT: EXPLORATORY OBSERVATIONAL STUDY

- Using virtual patients, facilitated by natural language processing, provides a valuable educational experience for learners. Generating a large, varied sample of realistic and appropriate responses for virtual patients is challenging. Artificial intelligence (AI) programs can be a viable source for these responses, but their utility for this purpose has not been explored.

A WHOLE-BODY PHYSIOLOGY MODEL TO INVESTIGATE RESPIRATORY FUNCTION DURING EXERCISE ACROSS

DIFFERENT AGE COHORTS

- There is a limitation in understanding complete cardiopulmonary function during moments of exhaustive exercise due to invasive measurement techniques. We asked how cardiopulmonary function is perturbed during times of exercise in different age cohorts: 6–11 and 11–18. We sought to broadly analyze how age and oxidative stress during exercise differ across age cohorts. Methods: We present a whole-body physiology model that connects the nervous, cardiovascular, respiratory, and oxygen transport and binding systems. We connect these models using a lumped parameter representation of the cardiovascular and respiratory systems. Results: we observe distinct age-related difference in physiological response to exercise. These responses consist of respiratory, cardiovascular, and nervous system perturbations that are distinct across these age groups.

BIOMEDICAL MODELING GROUP LEADER (SENIOR ENGINEER, DISTINGUISHED MEMBER OF THE TECHNICAL STAFF)

February 2016 - October 2021

- Lead a multidisciplinary team across 4 different projects
- In charge of agile development processes, product roadmap, delivery scheduling, and direct communication with government customers
- Led and won multiple research and development funds through Defense Health Agency and Army Research Lab grants
- Principal investigator of the BioGears, BurnCare training application, and the traumatic brain injury angiogenesis projects
- Organized teaming across three research hospitals and multiple small businesses
- Communicate research progress through multiple conferences and peer reviewed publications, including the BioGears 2020 conference
- Oversaw implementation of all models associated with BioGears releases 7.0-7.5
